Abstract

Pharmacy education has undergone significant transformation over the past few decades, evolving from a product-centered model to a patient-centered approach aligned with the expanding role of pharmacists in primary care settings. As healthcare systems increasingly emphasize preventive care, chronic disease management, and patient engagement, pharmacists are becoming integral members of primary healthcare teams. This shift necessitates changes in pharmacy education to equip future pharmacists with the clinical, communication, and interpersonal skills required for effective pharmacist-patient interactions. This article explores the relationship between pharmacy education and the future of pharmacist-patient interactions in primary care. It examines current educational frameworks, identifies gaps between academic training and real-world practice, and highlights emerging pedagogical strategies aimed at strengthening patient-centered competencies. A mixed-methods research design is proposed to assess perceptions of pharmacy students, educators, and practicing pharmacists regarding educational preparedness and interactional skills. The findings emphasize that enhanced communication training, experiential learning, interprofessional education, and the integration of technology are essential for preparing pharmacists for expanded roles in primary care. The study concludes that reforming pharmacy education to prioritize patient interaction skills is critical for improving healthcare outcomes, strengthening trust between pharmacists and patients, and advancing the profession's role in primary care delivery.

1. Introduction

Primary care forms the backbone of effective and sustainable healthcare systems worldwide (Sarbasheva, Makhieva et al. 2024). It emphasizes disease prevention, health promotion, early diagnosis, and the long-term management of chronic conditions, thereby reducing the burden on secondary and tertiary healthcare services. In this context, healthcare delivery increasingly relies on multidisciplinary teams in which different professionals collaborate to provide comprehensive, patient-centered care. Among these professionals, pharmacists have emerged as key contributors to primary care due to their accessibility, medication expertise, and expanding scope of practice (Albanese, Rouse et al. 2010). Traditionally, the role of pharmacists was largely confined to the preparation, dispensing, and supply of medicines. However, over the past few decades, this role has undergone a profound transformation. Pharmacists are now actively involved in direct patient care activities such as medication therapy management, chronic disease monitoring, preventive health services, and health education. This shift reflects broader changes in healthcare systems that prioritize patient safety, quality of care, and cost-effectiveness (Scott 2009). As a result, pharmacist–patient interactions have become central to contemporary pharmaceutical practice, particularly within primary care settings.

Pharmacists are often the most accessible healthcare professionals, with patients frequently consulting them without prior appointments (Tsuyuki, Beahm et al. 2018). This accessibility places pharmacists in a unique position to influence patient behavior, promote rational medicine use, and identify potential medication-related problems at an early stage. Effective communication between pharmacists and patients is therefore essential. High-quality interactions can improve medication adherence, reduce medication errors, enhance patient satisfaction, and ultimately lead to better health outcomes. Conversely, poor communication may result in misunderstandings, non-adherence, and adverse health consequences. The quality of pharmacist–patient interactions is closely linked to the nature and quality of pharmacy education. Pharmacy education plays a critical role in shaping professional identity, clinical competence, and communication skills. Historically, pharmacy curricula were heavily oriented toward pharmaceutical sciences, including pharmaceutics, pharmacology, medicinal chemistry, and pharmaceutical analysis (Chisholm 2019). While these disciplines remain fundamental to professional competence, they alone are insufficient to meet the demands of modern, patient-centered healthcare. Limited emphasis on communication skills, ethical reasoning, cultural competence, and clinical decision-making has been identified as a gap in traditional pharmacy education models. In response to evolving healthcare needs, pharmacy education has gradually shifted toward a more patient-centered and clinically oriented approach. Many educational programs have incorporated experiential learning, clinical rotations, problem-based learning, and interprofessional education to better prepare students for real-world practice (Chang and Hwang 2023). These reforms aim to equip future pharmacists with not only technical knowledge but also the interpersonal and professional skills required for effective patient engagement. Nevertheless, concerns remain regarding whether current educational frameworks adequately prepare graduates for complex pharmacist–patient interactions in primary care environments (Mills, Madden et al. 2022).

Within primary care, pharmacists play an increasingly important role in the management of chronic diseases such as diabetes,

hypertension, asthma, and cardiovascular conditions (George, Molina et al. 2010). These diseases require long-term therapy, ongoing monitoring, and continuous patient education. Managing such conditions effectively demands more than clinical knowledge; it requires empathy, active listening, cultural sensitivity, ethical awareness, and the ability to build trusting relationships with patients (Epner and Baile 2012). Pharmacists must be capable of addressing patients' concerns, beliefs, and expectations while tailoring therapeutic recommendations to individual needs. Furthermore, modern primary care increasingly relies on team-based and collaborative care models. Pharmacists are expected to work closely with physicians, nurses, and other healthcare professionals to optimize treatment outcomes. Effective collaboration depends on strong communication skills and professional confidence, which are developed during undergraduate and postgraduate education. Pharmacy education must therefore prepare students to function effectively within interdisciplinary teams while maintaining a strong focus on patient-centered care (Haines, DeHart et al. 2011).

Against this backdrop, it is essential to critically examine the role of pharmacy education in shaping the future of pharmacist–patient interactions in primary care. Understanding how educational experiences influence professional readiness, communication competence, and attitudes toward patient care can inform curriculum development and policy decisions. This article aims to explore the relationship between pharmacy education and pharmacist–patient interactions in primary care by reviewing existing literature, examining educational practices, and discussing research findings related to professional preparedness and patient-centered practice. By doing so, it seeks to contribute to ongoing discussions on how pharmacy education can be strengthened to meet the evolving demands of primary healthcare systems (Bheekie and Bradley 2016).

2. Literature Review

2.1 Evolution of Pharmacy Education

Pharmacy education has undergone a profound transformation over the past several decades, evolving from a product-centered discipline focused primarily on medication dispensing to a patient-centered profession emphasizing clinical care and therapeutic outcomes (Carli Lorenzini, Olsson et al. 2019). Traditionally, pharmacy curricula concentrated on pharmaceutical chemistry, pharmaceutics, pharmacognosy, and drug manufacturing, with limited attention to patient interaction or clinical decision-making. While this scientific foundation remains essential, the changing demands of healthcare systems have necessitated a broader educational focus that prepares pharmacists for active roles in patient care, particularly within primary care settings (Manolakis and Skelton 2010).

The introduction of the Doctor of Pharmacy (PharmD) degree in many countries marked a pivotal shift in pharmacy education (Kheir, Zaidan et al. 2008). The PharmD curriculum emphasizes clinical pharmacy, evidence-based practice, pharmacotherapy, and direct patient care experiences. Studies have shown that this educational model enhances pharmacists' clinical competence and confidence in patient-facing roles. Experiential learning components, such as clerkships and internships in hospitals and community pharmacies, are now integral parts of pharmacy education, allowing students to apply theoretical knowledge in real-world healthcare environments. Moreover, accreditation bodies and professional organizations increasingly advocate for competency-based education that includes communication skills, ethical reasoning, and patient counseling.

These developments reflect the growing recognition that pharmacists are not merely medication experts but essential healthcare providers who contribute to disease prevention, health promotion, and chronic disease management. As primary care continues to evolve toward integrated and team-based models, pharmacy education plays a critical role in shaping pharmacists' readiness to engage meaningfully with patients and other healthcare professionals (Ascione 2019).

2.2 Importance of Pharmacist–Patient Interaction

Pharmacist–patient interaction is a cornerstone of effective pharmaceutical care and a key determinant of positive health outcomes in primary care (Ascione 2019). Numerous studies have demonstrated that high-quality communication between pharmacists and patients leads to improved medication adherence, reduced medication-related problems, and enhanced patient satisfaction. Through counseling and education, pharmacists help patients understand their medications, including proper use, potential side effects, and the importance of adherence, thereby minimizing risks and optimizing therapeutic outcomes (Kumar 2024). Effective interactions also foster trust and shared decision-making, empowering patients to take an active role in managing their health. Research indicates that patients are more likely to follow treatment plans when pharmacists demonstrate empathy, listen attentively to patient concerns, and tailor information to individual needs. This is particularly important in the management of chronic diseases, where long-term adherence and lifestyle modifications are critical to disease control (Willett, Koplan et al. 2006).

Furthermore, pharmacist–patient communication contributes to early identification of medication-related issues, such as adverse drug reactions or drug–drug interactions. In primary care settings, pharmacists often serve as accessible healthcare providers who can identify potential problems before they escalate, reducing the burden on physicians and healthcare systems. As a result, communication skills are increasingly regarded as core competencies for pharmacists, underscoring the importance of educational strategies that prioritize interpersonal and counseling skills (Hargie, Morrow et al. 2000).

2.3 Gaps in Educational Preparation

Despite significant advancements in pharmacy education, literature consistently reports gaps between academic training and real-world practice. Many pharmacy graduates express feelings of inadequacy when engaging in complex patient interactions, particularly in primary care environments that require advanced communication, cultural competence, and clinical judgment. These gaps are often attributed to limited exposure to authentic patient encounters during training and insufficient emphasis on soft skills within traditional curricula. Studies highlight that while students may possess strong pharmacological knowledge, they often struggle with counseling patients from diverse cultural and linguistic backgrounds, addressing sensitive health issues, or managing patients with multiple chronic conditions. Additionally, the increasing complexity of healthcare systems requires pharmacists to navigate ethical dilemmas, health literacy challenges, and time constraints, areas that may not be adequately addressed in conventional educational models (Alyami, Al Sulayyim et al.).

Another commonly cited challenge is the variability in experiential learning quality. Inconsistent supervision, limited patient interaction opportunities, and a lack of structured feedback during clinical placements can hinder skill development. These findings suggest a need for more standardized and comprehensive approaches to

experiential education that better prepare students for the realities of primary care practice.

2.4 Educational Innovations and Interprofessional Learning

In response to identified educational gaps, pharmacy education has increasingly embraced innovative teaching and learning strategies designed to enhance clinical competence and communication skills (Katoue and Schwinghammer 2020). Simulation-based learning, including role-playing, standardized patients, and virtual simulations, allows students to practice patient interactions in a controlled and supportive environment. Evidence suggests that such approaches improve confidence, communication proficiency, and clinical reasoning. Problem-based learning (PBL) has also gained prominence, encouraging students to apply knowledge collaboratively to real-life clinical scenarios. This method fosters critical thinking, self-directed learning, and teamwork, all of which are essential for effective pharmacist–patient interactions in primary care. Additionally, interprofessional education (IPE) has emerged as a key strategy for preparing pharmacists to work within multidisciplinary healthcare teams. By learning alongside medical, nursing, and allied health students, pharmacy students develop a clearer understanding of professional roles, enhance communication skills, and cultivate mutual respect (Horsburgh, Lamdin et al. 2001).

The integration of digital health technologies into pharmacy education further reflects contemporary practice trends (Alsulami 2025). Training in telepharmacy, electronic health records, and digital communication tools equips future pharmacists to engage with patients in both face-to-face and virtual care settings. Collectively, these educational innovations represent a shift toward a more holistic and practice-oriented approach, aiming to bridge the gap between education and the evolving demands of primary care (GUPTA and GAUTAM).

3. Methodology

3.1 Research Design

This study employs a mixed-methods research design to comprehensively examine the influence of pharmacy education on pharmacist–patient interactions in primary care settings. A mixed-methods approach was selected to capture both the breadth and depth of perspectives related to educational preparedness, communication competence, and professional confidence. By integrating quantitative and qualitative data, the study provides a more nuanced understanding of how educational experiences translate into real-world patient care practices. The quantitative component focuses on measuring perceptions and self-reported competencies among pharmacy students and practicing pharmacists, while the qualitative component explores lived experiences, contextual factors, and educational insights from multiple stakeholders. The convergence of these methods enhances the validity of findings through triangulation and allows for a richer interpretation of results.

3.2 Study Population and Sampling

The study population includes three key groups: final-year pharmacy students, practicing pharmacists working in primary care settings, and pharmacy educators involved in curriculum development and instruction. Participants are selected using purposive sampling to ensure that individuals with relevant educational and professional experience are included. This sampling strategy enables the collection of informed and meaningful data aligned with the study objectives. Final-year students are targeted

due to their proximity to professional practice and extensive exposure to both theoretical and experiential learning. Practicing pharmacists are recruited from community pharmacies and primary care clinics, where patient interaction is a core professional responsibility. Pharmacy educators are included to provide insights into curricular design, teaching strategies, and perceived challenges in preparing students for patient-centered roles.

3.3 Data Collection Methods

3.3.1 Quantitative Data Collection

Quantitative data are collected through a structured, self-administered questionnaire distributed electronically (Burns, Duffett et al. 2008). The questionnaire is designed based on existing literature and validated instruments related to communication skills, educational preparedness, and professional confidence. It consists of closed-ended questions and Likert-scale items assessing participants' perceptions of their educational experiences, communication training, and readiness for pharmacist-patient interactions in primary care. The survey also gathers demographic information, including age, gender, academic background, and years of professional experience, to contextualize responses and allow for subgroup analysis. Prior to distribution, the questionnaire is pilot-tested to ensure clarity, reliability, and content validity.

3.3.2 Qualitative Data Collection

Qualitative data are collected through semi-structured interviews conducted with a subset of participants from each group. An interview guide is developed to explore participants' experiences with pharmacy education, perceptions of communication training, challenges encountered in patient interactions, and recommendations for curricular improvement. Semi-structured interviews allow flexibility to probe emerging themes while maintaining consistency across participants. Interviews are conducted either face-to-face or via secure online platforms, depending on participant availability and location. All interviews are audio-recorded with participant consent and transcribed verbatim to ensure accuracy and completeness of data.

3.4 Data Analysis

Quantitative data are analyzed using statistical software to perform descriptive and inferential analyses. Descriptive statistics, including frequencies, means, and standard deviations, are used to summarize participant characteristics and response patterns. Inferential statistics, such as correlation analysis and comparative tests, are applied to examine relationships between educational experiences and perceived communication competence and confidence in patient interactions. Qualitative data are analyzed using thematic analysis following a systematic and iterative process. Transcripts are read multiple times to achieve familiarization, after which initial codes are generated. These codes are then organized into broader themes reflecting key aspects of pharmacy education, experiential learning, communication skills development, and professional identity formation. To enhance credibility, themes are reviewed and refined through peer discussion and cross-checking.

3.5 Ethical Considerations

Ethical approval for the study is obtained from the relevant institutional review board prior to data collection. All participants are provided with detailed information about the study objectives, procedures, and their rights as participants. Informed consent is obtained before participation, and confidentiality is strictly maintained. Participant anonymity is ensured by assigning unique identification codes, and all data are securely stored and used solely for research purposes.

4. Results and Discussion

4.1 Quantitative Results

The quantitative findings reveal important insights into how pharmacy education influences pharmacist-patient interactions in primary care. Overall, survey responses indicate that pharmacy education provides a strong foundation in pharmaceutical sciences and clinical knowledge. A majority of participants expressed confidence in their understanding of pharmacotherapy, medication safety, and disease management. However, notable gaps were identified in areas related to communication skills and patient-centered interaction. Survey results show that participants who reported extensive experiential learning—such as clinical rotations, community pharmacy placements, and patient counseling opportunities—demonstrated significantly higher confidence in patient interactions compared to those whose education was primarily classroom-based. Final-year students and practicing pharmacists with greater exposure to real-world practice settings reported improved abilities in explaining medication use, addressing patient concerns, and managing complex interactions involving chronic diseases. In contrast, respondents with limited practical exposure expressed discomfort when counseling patients, particularly in situations requiring empathy, cultural sensitivity, or shared decision-making. The data further suggest that experiential learning plays a critical role in bridging the gap between theoretical knowledge and practical application. Participants emphasized that simulated learning alone was insufficient without meaningful patient contact. These findings highlight the importance of integrating practice-based learning throughout pharmacy education to strengthen communication competence and professional confidence.

4.2 Qualitative Findings

The qualitative analysis identified several recurring themes that provide deeper insight into the quantitative findings. One prominent theme was the importance of early and sustained exposure to patient care. Participants consistently reported that early interaction with real patients helped them develop communication skills, professional confidence, and a patient-centered mindset. Those who encountered patients only during later stages of their education felt less prepared for independent practice. Another key theme was the role of mentorship during clinical placements. Participants highlighted that guidance from experienced pharmacists significantly influenced their ability to communicate effectively with patients. Supportive mentors who modeled patient-centered communication, ethical practice, and reflective learning were seen as instrumental in professional development. Conversely, inconsistent supervision and limited feedback were reported as barriers to skill acquisition.

The need for structured communication skills training also emerged as a critical issue. Educators emphasized that communication and interpersonal skills should be formally taught, practiced, and assessed rather than assumed to develop naturally. Practicing pharmacists stressed the importance of reflective learning and continuous professional development, noting that communication skills must be refined throughout one's career to adapt to evolving patient needs and healthcare environments.

4.3 Discussion

The findings of this study align closely with existing literature emphasizing the multidimensional nature of pharmacist competence in primary care. While scientific and clinical knowledge remain essential, the ability to communicate effectively with patients is

increasingly recognized as equally important. The perceived deficiencies in communication-focused training reported by participants support previous research indicating a mismatch between educational preparation and practice demands. The results reinforce the argument that patient-centered competencies must be embedded throughout pharmacy curricula, rather than confined to isolated courses or short training modules. Experiential learning, mentorship, and structured assessment of soft skills are critical components of effective education. Moreover, the findings highlight the growing importance of digital communication skills, as telehealth services, electronic consultations, and digital health platforms become integral to primary care delivery. Pharmacy education must therefore incorporate training in digital professionalism, virtual patient counseling, and electronic health communication. Overall, this study underscores the need for continuous curriculum reform to ensure that pharmacy graduates are not only clinically competent but also confident, empathetic, and effective communicators. Strengthening these competencies will enhance pharmacist–patient interactions, improve health outcomes, and support the evolving role of pharmacists within primary care systems.

5. Conclusion

Pharmacy education plays a pivotal role in shaping the quality and effectiveness of pharmacist–patient interactions in primary care. As pharmacists increasingly undertake expanded clinical and advisory responsibilities, their ability to communicate clearly, establish patient trust, and deliver individualized, patient-centered care has become essential. This study highlights that while contemporary pharmacy education provides a strong scientific and clinical foundation, gaps remain in preparing graduates for the complex interpersonal demands of primary care practice. The findings emphasize the importance of strengthening communication-focused training, expanding experiential and practice-based learning opportunities, and integrating interprofessional education into pharmacy curricula. Early and sustained exposure to real-world clinical settings, combined with effective mentorship and reflective learning, can significantly enhance pharmacists' confidence and competence in patient interactions. Furthermore, the growing use of digital health technologies in primary care underscores the need to equip future pharmacists with skills in virtual communication and digital professionalism. Overall, aligning pharmacy education with the evolving needs of primary care is essential for ensuring that pharmacists are not only clinically knowledgeable but also effective communicators and patient advocates. By prioritizing patient-centered competencies and continuous curricular improvement, pharmacy education can better prepare pharmacists to contribute meaningfully to healthcare teams and to improved patient outcomes in increasingly complex healthcare systems.
